

langsci-avm

Felix Kopecky*

Version 0.3.0 – February 20, 2023

1 Introduction

`langsci-avm` allows typesetting of feature structures, or *attribute-value matrices* (AVM), for use in linguistics. The package provides a minimal and easy to read syntax. The package serves the same purpose as Christopher Manning’s `avm` package, but shares no code base with that package. There is a conversion guide in Section 4.6.

To start using `langsci-avm`, place `\usepackage{langsci-avm}` in your preamble.

This documentation is structured as follows: Section 2 describes the input syntax for AVMs and their parts. Ways to customise your AVM’s layout follow in Section 3, and selected usage cases are presented in Section 4. There’s also an administrative and \TeX nicol appendix at the end of this document, in case you are interested.

1.1 Example

```
\avm{
  [ ctxt & [ max-qud \[
    sal-utt & \{ [ cat \[
      cont <ind & i> ] \}
    ]
  ]
}
```

$$\left[\text{CTXT} \left[\begin{array}{l} \text{MAX-QUD} \\ \text{SAL-UTT} \end{array} \left\{ \left[\begin{array}{l} \text{CAT} \\ \text{CONT} \end{array} \langle \text{IND } i \rangle \right] \right\} \right] \right]$$

1.2 Acknowledgements

Thanks to Phelype Oleinik for help on recursion and expansion with \LaTeX 3. Thanks to Ahmet Bilal Özdemir and Stefan Müller for their contributions in planning and testing this package.

*<mailto:felix.kopecky@langsci-press.org>. Please submit bug reports and feature requests to <https://github.com/langsci/langsci-avm/issues>.

2 Structuring AVMs

`\avm` `\avm` [*options*] {*structure*}

This root command of the package type sets AVMs in the document. In the {*structure*}, delimiter characters are processed to open and close (sub-)structures, as described in Section 2.1. Special elements (e.g. tags, operators, type descriptors) are described in Section 2.2. For a description of the layout *options*, see Section 3.

A *structure* is basically the content of a stylised `tabular`: The columns are separated by `&` and a new line is entered with `\\`.

2.1 Entering (sub-)structures within `\avm`

<code>[...]</code>	<code>[<structure >]</code>
<code><...></code>	<code>< structure ></code>
<code>(...)</code>	<code>(structure)</code>
<code>\{...\}</code>	<code>\{ structure \}</code>
<code>\[...\]</code>	<code>\[structure \]</code>

Updated: 2020-10-02 Within the scope of `\avm`, these delimiters create (sub-)structures that are enclosed by the respective delimiter. Due to the special meaning that curly braces have in \LaTeX , these are the only ones that need to be run with an escape token (`\`). It is currently possible to mix delimiters, e.g. with `<structure>`, but this may change in future versions.

`langsci-avm` expects your (sub-)structures to have *at most two columns*, so that for every line in each (sub-)structure, there should be no more than one `&`. It is recommended to have at least some lines with a `&` in your *structure*. Currently, display issues may appear in some structures if none are given – see the `align=false` option to remedy this effect.

<code>\avm{</code>	
<code>[< (\{ ... \}) >]</code>	$\llbracket \langle \{ \dots \} \rangle \rrbracket$
<code>}</code>	
<code>\avm{</code>	
<code>[\{ ... \} \\</code>	$\left[\left\{ \dots \right\} \right.$
<code>< (...), (...) >]</code>	$\langle \langle \dots \rangle, \langle \dots \rangle \rangle$
<code>}</code>	

<code>\[... \]</code>	<code>\[structure \]</code>
------------------------	------------------------------

New: 2020-10-02 Add a semantic bracket $\llbracket \langle structure \rangle \rrbracket$.

Warning: Semantic brackets are only available when the package option `[lfg]` is loaded (`\usepackage[lfg]{langsci-avm}`). Documents with this option can only be compiled with \XeLaTeX . If the `[lfg]` option is not present, `\[{structure} \]` will result in none delimiter output, but the {*structure*} will be printed nonetheless. (The semantic delimiters are not available in every font, and are currently not provided in standard \LaTeX documents. If you load the `[lfg]` option but do not provide the symbol (e.g. by using a font such as `libertinus`), the package `unicode-math` will automatically be loaded to provide the symbol.)

<hr/> <code>\lframe ... \rframe</code> <hr/>	<code>\lframe</code> $\langle structure \rangle$ <code>\rframe</code>
<hr/> New: 2021-03-03 <hr/>	Delimit a $\langle structure \rangle$ placed in a rectangular box, which is used in Fillmore & Kay's notation. It can be used like the other delimiters.

`\avm{`
`\lframe ... \rframe` \dots
`}`

The parameters of the frame can be adjusted with these options:

`framewidth = $\langle length \rangle$` (initially 1pt)
Width of the frame.

`framesep = $\langle length \rangle$` (initially 3pt)
Separation of the frame and its contents.

`!...!` $\langle text \rangle$!

Escapes the `avm` mode so that all delimiters can be used as usual characters. If you need `!` as a regular character, see Section 3 for how to change the `switch`.

2.2 Commands for tags, types, unusual lines, and relations

<hr/> <code>\tag</code> <hr/>	<code>\tag</code> $\{\langle identifier \rangle\}$
<code>\0</code>	<code>\0</code> , <code>\1</code> , <code>\2</code> , <code>\3</code> , <code>\4</code> , <code>\5</code> , <code>\6</code> , <code>\7</code> , <code>\8</code> , <code>\9</code>
<code>\1</code>	<code>\tag</code> puts its $\{\langle identifier \rangle\}$ in a box, more precisely an <code>\fbox</code> . Within the box, the <code>tags</code> font is applied. <code>\0</code> , <code>\1</code> , ..., <code>\9</code> are shortcuts to <code>\tag</code> and place the respective number in the
<code>...</code>	box. For example, <code>\4</code> is equivalent to <code>\tag{4}</code> . The shortcuts do not take any arguments.
<code>\9</code>	
<hr/> Updated: 2020-04-29 <hr/>	If you want to use this command outside an AVM, you can obtain, for example, 4 , by using <code>\avm{\4}</code> , or the equivalent $\{\fboxsep.25ex\fbox{\footnotesize 4}\}$.

`\avm{[attr1 & \4\`
`attr2 & \4[attr3 & val3\`
`attr4 & val4]]}` $\left[\begin{array}{c} \text{ATTR1 } \boxed{4} \\ \text{ATTR2 } \boxed{4} \left[\begin{array}{c} \text{ATTR3 } val3 \\ \text{ATTR4 } val4 \end{array} \right] \end{array} \right]$

<hr/> <code>\type</code> <hr/>	<code>\type*</code> $\{\langle type \rangle\}$
<code>\type*</code>	Will output the $\langle type \rangle$ in the <code>types</code> font (serif italics by default). The starred variant <code>\type*</code> will span the complete (sub-)structure and <i>can only be placed in the first column</i> of this structure. After the starred <code>\type*</code> , a <code>\</code> is recommended, but can usually be omitted.
<hr/> Updated: 2020-03-30 <hr/>	

`\avm{[\type*{A type spanning a line}`
`attr & [\type{type}]]}` $\left[\begin{array}{c} A \text{ type spanning a line} \\ \text{ATTR } [type] \end{array} \right]$

<hr/> <code>\id</code> <hr/>	<code>\id {⟨<i>id</i>⟩} {⟨<i>structure</i>⟩}</code>
<div>New: 2020-10-02 Updated: 2021-12-14</div>	A variant of <code>\substack</code> from <code>amsmath</code> , this command adds an identifier to the <code>{⟨<i>structure</i>⟩}</code> . The contents of <code>{⟨<i>id</i>⟩}</code> will be set in math mode by default, which is convenient given that they often contain variables with subscript indices. Multiple IDs should be separated by a new line, <code>\\</code> .

`\avm{⟨id⟩n1\\n2⟩{[subj\\pred&swim]}}`
$$\begin{matrix} \text{SUBJ} \\ \text{PREDE } swim \end{matrix}$$

The position of the `{⟨id⟩}` column relative to the `{⟨structure⟩}` and the alignment within the `{⟨id⟩}` column can be changed:

`id align = ⟨token⟩` (initially `l`)

Change the alignment of the column inserted by `\id`. Has to be a column specification. The most probable choices are `l` and `r`.

`id position = ⟨option⟩` (initially `south-west`)

Change the position of `\id`. In the standard setting `south-west`, the `\id` is placed in the lower left corner of the enclosed structure. When set to `south-east`, the contents are set to the lower right corner. Currently, only `south-west` and `south-east` are recognised inputs, and an error is raised when an unknown option is input.

<hr/> <code>\punk</code> <hr/>	<code>\punk {⟨<i>attribute</i>⟩}{⟨<i>type</i>⟩}</code>
<div>Updated: 2021-06-08</div>	Some <code>⟨<i>attributes</i>⟩</code> think that the layout of the other attributes in their community leaves no space for them to express their individuality. They desire a life outside the confines of the alignment defined by the others, while still remaining a member of the matrix. Technically, this is a line with no snapping to the column layout, but with spacing between the <code>⟨<i>attribute</i>⟩</code> and <code>⟨<i>type</i>⟩</code> . After <code>\punk</code> , a <code>\\</code> is obligatory if not in the last line.

`\avm{[attr1 & val1\\
 \punk{a quite long attr2}{val2}
 attr3 & val3\\
 attr4 & val4
]}`
$$\begin{matrix} \text{ATTR1 } val1 \\ \text{A QUITE LONG ATTR2 } val2 \\ \text{ATTR3 } val3 \\ \text{ATTR4 } val4 \end{matrix}$$

Hint: Also have a look at the option `align=false`.

<hr/> <code>\+</code> <hr/>	In the scope of <code>\avm</code> , <code>\+</code> comes out as “ \oplus ”. “ $+$ ” can be obtained normally. <i>In the earlier Version 0.1.0-beta, <code>+</code> produced “\oplus”.</i>
<div>Updated: 2020-03-16</div>	

<hr/> <code>\-</code> <hr/>	In the scope of <code>\avm</code> , <code>\-</code> comes out as “ \ominus ”. To use the “optional hyphenation” meaning of <code>\-</code> , please write <code>!\-!</code> , where <code>!</code> is your current <code>switch</code> token.
<div>New: 2020-03-17</div>	

<hr/> <code>\shuffle</code> <hr/>	In the scope of <code>\avm</code> , <code>\shuffle</code> is a shortcut for “ \circ ” to mark the shuffle relation.
<div>New: 2020-03-17</div>	

3 AVM layout

3.1 Defining styles

You can customise many aspects of how an AVM is printed, including the fonts or spacing between delimiters and content. You can apply them locally via the `[<options>]` of `\avm` or globally by using `\avmsetup`. And you can also define your own styles and use them via the `[<style = >]` option in `\avm`.

<code>\avmsetup</code>	<code>\avmsetup {<options>}</code>
------------------------	--

`{<options>}` is a comma-separated list of **key=value** settings. See the list below for all user-configurable options. The `{<options>}` are the same as in `\avm[<options>]`. When inserted in `\avm[<options>]`, they apply locally, and globally if given to `\avmsetup`. Local settings always override global ones, and you can have any feasible number of `\avmsetups` in your document. The scope of `\avmsetup` can be restricted through grouping.

<code>\avmdefinestyle</code>	<code>\avmdefinestyle {<name>} {<settings>}</code>
------------------------------	--

New: 2020-05-11

Instead of applying settings globally or per AVM, you can also define styles and assign them to AVMs, as in `\avm[style=<name>]{...}`. The `<settings>` are a comma-separated list of **key=value** settings, and should be a subset of the settings from `\avmsetup`. For example, the following `plain` style highlights neither attributes, values, nor types:

```
\avmdefinestyle{plain}{attributes=\normalfont,
                        values=\normalfont,
                        types=\normalfont}
```

The style is applied with `\avm[style=plain]{...}`.

Now to the list of settings:

style = `<name>` (initially empty)

In addition to any style that you possibly define yourself, a style **narrow** is pre-defined in the package (see Section 4.1).

align = `<choice>` (initially **true**)

Controls whether the columns in the AVM and its substructures should be aligned (snapping to the grid) or not. Aligned AVMs are separated by **columnsep**, non-aligned are separated by **vectorsep**.

stretch = `<factor>` (initially 0.9)

Define `\arraystretch`, i.e. a factor in the determination of line height.

columnsep = `<length>` (initially 0.5ex)

Define the `\tabcolsep`, i.e. horizontal space between columns. The first and second column will have `0\columnsep` to the left and right, respectively. Between the two the distance is `2\columnsep`. Using relative units (like **ex** or **em**) may be a good idea so that **columnsep** scales well with changes in font size.

vectorsep = `<length>` (initially 1em)

Define the horizontal separation between columns in non-aligned matrices (see option **align**).

`delimfactor = $\langle factor \rangle$` (initially 1000)
 Sets `\delimfactor`. The calculation for the minimum height of a delimiter is $y \cdot f / 1000$, where y is the height of the content and f the value of `delimfactor`. The default 1000 ensure that the delimiters' height is at least that of the structure.

`delimfall = $\langle length \rangle$` (initially 0pt)
 Controls `\delimitershortfall`, i.e. the maximum height that the delimiters can be shorter than the enclosed structure. The default 0pt ensure that the delimiters are not shorter than the contents.

`extraskip = $\langle length \rangle$` (initially `\smallskipamount`)
 If a substructure is immediately followed by a `\\`, an extra amount of vertical skip is added so that the content of the next line, possibly another delimiter, does not clash with the delimiter in that line. This automatic skip insertion can be circumvented with placing a `\relax` before the linebreak, i.e. `\relax\\`.

`attributes = $\langle font settings \rangle$` (initially `\scshape`)
 The font for attributes, i.e. the first column of each structure.

`values = $\langle font settings \rangle$` (initially `\itshape`)
 The font for values, i.e. the second column of each structure.

`types = $\langle font settings \rangle$` (initially `\itshape`)
 The font used in `\type` and `\type*`.

`tags = $\langle format settings \rangle$` (initially `\footnotesize`)
 The font (size) used in `\tag` and the shortcuts `\1...\9`.

`switch = $\langle token \rangle$` (initially `!`)
 Define the escape token. Change this if you need to use “!” as a text glyph.

`customise = $\langle settings \rangle$` (initially empty)
 An interface to input custom commands to be run at the beginning of every `\avm`.

3.2 Drawing edges between AVM contents

It is possible to make AVM contents available to `tikz`, so that they can be referenced in a `tikzpicture`. To enable this feature, `langsci-avm` has to be loaded with the option `[tikz]`:

```
\usepackage[tikz]{langsci-avm}
```

Additionally, `avm` environments on which `tikz` is to be used need to have the `[pic]` option present:

```
\avm[pic] {...}
```

Only the parts of an AVM that are specifically marked will be known to `tikz`. To mark a part of an AVM to be used by `TikZ`, use `\node`:

<code>\node</code>	<code>\node {\langle id \rangle} {\langle contents \rangle}</code>
--------------------	--

New: 2020-09-23

`{\langle id \rangle}` serves as part of the node’s identifier in a `tikzpicture`. It will be prefixed, and it’s complete name will be `avm-n-\langle id \rangle`, where `n` is the counter of `\avm` in your document that have the `[pic]` option enabled and that don’t have a `picname` (see below). `n` starts at 1. For example, a `\node` named “pretty-node” in the fourth `[pic]`-enabled `avm` in your document will be `avm-4-pretty-node`. Note that `\node` will register the complete name globally in your document, and so can’t be declared by other `tikz` nodes.

This behaviour can be adjusted by passing a `[picname = \langle avm’s name \rangle]` to `\avm`. E.g., `\nodes` within `\avm[pic, picname=example1]` will have a full name pattern of `example1-\langle id \rangle`. Named `\avms` do *not* raise the `n` mentioned in the last paragraph.

Any (sub-)structure can be placed into `{\langle contents \rangle}`. It could be just a value, an attribute’s name, or parts thereof, but whole (sub-)structures can be part of `{\langle contents \rangle}` as well.

A `tikzpicture` with options `[remember picture, overlay]` enabled can reference `langsci-avm`’s `\nodes`. This way, TikZ’ extensive drawing abilities are available for the decoration of AVMs. Here’s a very simple example document:

```

\documentclass{article}
\usepackage{tikz}{langsci-avm}
\usepackage{tikz} % optional, since langsci-avm will load tikz if option
                  % tikz is present
\usetikzlibrary{arrows,arrows.meta}

\avm[pic]{[ subj & \1\
          comps & <\node{gap}{gap-ss}> \bigskip\
          \node{phon}{phon} & <\1 \+ \2>
          ]}

\begin{tikzpicture}[remember picture,overlay]
  \path[{Stealth[]}--{Stealth[]},gray,dashed,in=90,out=270]
    (avm-1-gap.south) edge (avm-1-phon.north);
\end{tikzpicture}

```

3.3 Defining input patterns

<code>\avmdefinecommand</code>	<code>\avmdefinecommand {⟨name⟩} [⟨label⟩] {⟨settings⟩}</code>
--------------------------------	--

New: 2020-06-29

Structures often follow specific patterns. For example, AVMs often have a PHON attribute, which is mapped to a list, the entries of which are in italics. `\avmdefinecommand` can account for this and other input patterns. For example,

```
\avmdefinecommand{custom}{...}
```

will create a command `\custom` available only in the scope of `\avm` (this means that you can have a different meaning in the rest of your document). The `⟨settings⟩` will then be applied to the scope in which `\custom` is called. If an optional `⟨label⟩` is given, the label will be printed, in the current font, before the `⟨settings⟩` are applied.

`\custom` generated in this way automatically advances to the value column after the `⟨label⟩` is printed. This means that commands generated with `\avmdefinecommand` should be called in the attribute column of an existing structure. This behaviour can be circumvented with the starred variant `\name*`, which is automatically generated by `\avmdefinecommand` as well. However, it seems advisable to use the starred variants sparingly.

Here's an example for the aforementioned phon pattern:

```
\avmdefinecommand{phon}[phon]
{
  attributes = \itshape,
  delimfactor = 900,
  delimfall = 10pt
}
```

This creates a command `\phon` (and the variant `\phon*`) within the scope of any `\avm`. It will print the label `phon` in the current font and then apply three settings locally: italics for the attribute (first) column, and two settings for very narrow delimiter fitting.

This results in:

<pre>\avm{ [\type*{word} \phon <lin'gwistiks>\\ synsem & [...] }</pre>	$\left[\begin{array}{ll} word & \\ PHON & \langle lin'gwistiks \rangle \\ SYNSEM & [...] \end{array} \right]$
--	--

Note that any other structure type would have worked instead of `⟨⟩`. But `⟨⟩` and any other markers for sub-structures are left unchanged by `\phon` and other custom commands. This is why the *attribute* font is changed by `\phon`, although *lin'gwistiks* is technically a value. Remember that `<` creates a new list sub-substructure, and the first content is printed in its attribute font.

4 Applications

4.1 Spacing and size of delimiters

`langsci-avm` automatically detects if the end of a sub-structure is followed by a line break. This is useful to find cases in which two sub-structures are printed immediately below each other, and to add extra spacing (the `extraskip` from the options). This automatic detection can be suppressed with `\relax`. See below for the effect of that detection:

<pre>\avm{[[attr1 & val1 \\ attr2 & val2] \\ [attr1 & val1 \\ attr2 & val2]]}</pre>	<pre>\avm{[[attr1 & val1 \\ attr2 & val2] \relax\\ [attr1 & val1 \\ attr2 & val2]]}</pre>
$\left[\begin{array}{l} \left[\begin{array}{l} \text{ATTR1 } val1 \\ \text{ATTR2 } val2 \end{array} \right] \\ \left[\begin{array}{l} \text{ATTR1 } val1 \\ \text{ATTR2 } val2 \end{array} \right] \end{array} \right]$	$\left[\begin{array}{l} \left[\begin{array}{l} \text{ATTR1 } val1 \\ \text{ATTR2 } val2 \end{array} \right] \\ \left[\begin{array}{l} \text{ATTR1 } val1 \\ \text{ATTR2 } val2 \end{array} \right] \end{array} \right]$

If many delimiters are nested, this occasionally results in larger delimiter sizes. There is a pre-defined `narrow` style that resets `delimfall` (to 5pt) and `delimfactor` (to 997), which are the values recommended in the *TEXbook*. This results in a more compact appearance:

<pre>\avm{[attr \{<\1>\}]]}</pre>	<pre>\avm[style=narrow]{[attr \{<\1>\}]]}</pre>
$[\text{ATTR} \langle \{\boxed{1}\} \rangle]$	$[\text{ATTR} \langle \{\boxed{1}\} \rangle]$

4.2 Disjunctions and other relations

Sometimes AMVs are placed beside other content to express disjunctions or other relations. In `langsci-avm` this is done naturally:

<pre>\avm{[attr1 & val1\\ attr2 & val2\\ attr3 & val3]] \$ \lor\$ \avm{[attr1' & val1'\\ attr2' & val2'\\ attr3' & val3'\\]]}</pre>	$\left[\begin{array}{l} \text{ATTR1 } val1 \\ \text{ATTR2 } val2 \\ \text{ATTR3 } val3 \end{array} \right] \vee \left[\begin{array}{l} \text{ATTR1'} val1' \\ \text{ATTR2'} val2' \\ \text{ATTR3'} val3' \end{array} \right]$
<pre>\textit{sign} \$ \to\$ \avm{[attribute1 & value1\\ attribute2 & value2\\ attribute3 & value3]}</pre>	$sign \rightarrow \left[\begin{array}{l} \text{ATTRIBUTE1 } value1 \\ \text{ATTRIBUTE2 } value2 \\ \text{ATTRIBUTE3 } value3 \end{array} \right]$

4.3 Use as a vector

It's possible to use `langsci-avm` for feature vectors rather than matrices, as may be useful in generative grammar.

$$\backslash\text{avm}[\text{attributes}=\text{\normalfont}]{[v1\backslash\backslash v2\backslash\backslash v3]}\$\varphi$$

4.4 Combinations with `gb4e`, `expex`, and `linguex`

This package works fine with `gb4e` and its fork `langsci-gb4e`. To align the example number at the top of your structure, please use `\attop` from `gb4e`:

```
\begin{exe}
  \ex\attop{
    \avm{[ attr1 & val1\backslash
          attr2 & val2\backslash
          attr3 & val3]}
  }
\end{exe}
```

$$(1) \begin{bmatrix} \text{ATTR1} & \text{val1} \\ \text{ATTR2} & \text{val2} \\ \text{ATTR3} & \text{val3} \end{bmatrix}$$

The same can be achieved with `expex` using `\envup` from `lingmacros` (see below) or using this *experimental* syntax:

```
\ex \vtop{\strut\vskip-\baselineskip{
  \avm{[ attr1 & val1\backslash
        attr2 & val2\backslash
        attr3 & val3]}
}}
\xe
```

Examples typed with `linguex` can be combined with `\envnup` from `lingmacros` to align AVMs (many thanks to Jamie Findlay for pointing this out):

```
\ex. \envnup{\avm{[ attr1 & val1\backslash
                  attr2 & val2\backslash
                  attr3 & val3]}
}
```

4.5 Combinations with `forest`

This package also works fine with `forest`. As per the `forest` documentation, it is recommended to protect any `\avm`-statements with `{}` in nodes:

```
\begin{forest}
  [A [B] [{\avm{[attr1 & val1\backslash
                attr2 & val2\backslash
                attr3 & val3]}} ] ]
\end{forest}
```

$$\begin{matrix} & A \\ & \swarrow \searrow \\ B & \begin{bmatrix} \text{ATTR1} & \text{val1} \\ \text{ATTR2} & \text{val2} \\ \text{ATTR3} & \text{val3} \end{bmatrix} \end{matrix}$$

It may happen that extensive AVMs protrude into the space reserved for other forest nodes or edges. In this case, the forest setting for `children = {anchor=north}` may be useful: (If you like, try this tree without that setting.)

```

\begin{forest}
  [A, for children = {anchor=north}
    [B] [{\avm{[attr1 & val1\\
      attr2 & a long value val2\\
      attr3 & val3\\
      attr4 & val4\\
      attr5 & val5]}} ]
  ]
\end{forest}

```

4.6 Switching from Christopher Manning’s `avm` package

Switching from `avm` to `langsci-avm` will require some, though hopefully minimal, changes to the code. In particular, `langsci-avm` doesn’t distinguish between “active” and “passive” modes, there is now a single way of sorting (see `\type`, which replaces `\asort` and `\osort`), and tags are now produced without `@` (`\4` instead of `@4`, etc.).

Paths can be printed with a normal `|`, and \oplus and other relation symbols can be input more easily (see Section 2.1), though the package will also work with `$$` and `$(\oplus)`.

5 Caveats and planned features

1. There are currently no error messages. If you do not receive the intended output, please make sure that your code fits the syntax described in this documentation. If your code is fine but the output is not, please submit a bug report or feature request at <https://github.com/langsci/langsci-avm/issues>.

These features are planned for the future:

2. A check whether the delimiters are balanced, i.e. whether all (sub-)structures are closed by a `]`, `}`, etc.
3. Improve the appearance of (very) large angle brackets so that they vertically span the complete structure they enclose, maybe using `scalerel`.

6 Implementation

```

1 <*package>
2 <@@=avm>
3 \RequirePackage{xparse}[2022/03/26]
4 \RequirePackage{array}
5 \ProvidesExplPackage {langsci-avm}
6   {2023-02-20} {0.3.0}
7   {AVMs and feature structures}

20   settings.
21 }

```

Let's first check for package options.

```

22 \bool_new:N \l__avm_lfg_bool
23 \bool_new:N \l__avm_tikz_bool
24 \DeclareOption{tikz}{ \bool_set_true:N \l__avm_tikz_bool }
25 \DeclareOption{lfg}{ \bool_set_true:N \l__avm_lfg_bool }
26 \ProcessOptions\relax

```

Handling for the TikZ package option.

```

27 \bool_if:NT \l__avm_tikz_bool
28 {
29   \RequirePackage{tikz}
30   \newcounter{l__avm_picture_counter}
31   \tl_new:N \l__avm_picture_name_prefix_tl
32 }

```

Handling for the LFG package option: If the semantic bracket is not available at the end of the preamble (i.e.) it was not loaded by another package, load unicode-math to provide the symbol.

```

33 \bool_if:NT \l__avm_lfg_bool
34 {
35   \cs_if_exist:NF \lBrack
36   {
37     \RequirePackage{etoolbox}
38     \AtEndPreamble { \RequirePackage{unicode-math} }
39   }
40 }

```

\avm This document command initialises an AVM. The first, optional argument is a key-value list of settings (see `\keys_define:nn` below) and the second is the AVM itself, given in the syntax described in this documentation.

`\avm` enters a group so that keys- and macro-assignments remain local. It then initialises the commands and shortcuts and any user customisation, sets its mode to `true` and assigns the keys as given in the optional argument (if any). After the parser `__avm_parse:n` is called, the group is closed.

```

41 \NewDocumentCommand{\avm}{ O{} +m }
42 {
43   \c_group_begin_token
44   \keys_set:nn { avm } { #1 }
45   \__avm_initialise_document_commands:
46   \__avm_initialise_custom_commands:
47   \tl_use:N \l__avm_defined_commands_tl
48   \__avm_mode_switch:
49   \__avm_parse:n { #2 }

```

```

50   \c_group_end_token
51 }

```

(End definition for `\avm`. This function is documented on page 2.)

`\l__avm_mode_bool` We need an auxiliary variable to store the current mode. `\l__avm_parens_tracker` is a stack for a future check whether the delimiters given to `\avm` are balanced. `\l__avm_defined_commands_tl` is a token list that stores any commands provided by the user via `\avmdefinecommand`. The box `\l__avm_fillmore_kay_box` is used as a temporary storage to realise Fillmore & Kay's notation.

```

52 \bool_new:N \l__avm_mode_bool
53 \seq_new:N \l__avm_parens_tracker
54 \tl_new:N \l__avm_defined_commands_tl
55 \box_new:N \l__avm_fillmore_kay_box
56 \tl_new:N \l__avm_parsed_tl
57 \int_new:N \l__avm_mode_switch_character_int

```

(End definition for `\l__avm_mode_bool` and others.)

`\avmsetup` Forward the key-value settings given as the optional argument to `\avm` to the keys defined in `\keys_define:nn { avm }`. For the meaning of these keys and initial values, see Section 2.

```

58 \NewDocumentCommand{\avmsetup}{ m }
59 { \keys_set:nn { avm } { #1 } }
60
61 \keys_define:nn { avm }
62 {

112  }

```

(End definition for `\avmsetup`. This function is documented on page 5.)

`\avmdefinestyle` Define a style to be used together with the `style` key.

```

113 \NewDocumentCommand{\avmdefinestyle}{ m m }
114 {
115   \keys_define:nn { avm }
116   {
117     style / #1 .code:n = { \keys_set:nn { avm } { #2 } }
118   }
119 }

```

(End definition for `\avmdefinestyle`. This function is documented on page 5.)

`\avmdefinecommand` A factory function that creates commands for the layout of sub-structures and saves them to `\l__avm_defined_commands_tl`. The first argument describes the command's name, the second any (optional) label. The manufactured definitions are activated in the AVM group so that they remain local.

```

120 \NewDocumentCommand{\avmdefinecommand}{ m O{ } m }
121 {
122   \tl_put_right:Nn \l__avm_defined_commands_tl
123   {
124     \exp_args:Nc \DeclareDocumentCommand { #1 } { s }
125     {
126       #2 \IfBooleanF { ##1 } { & } \avmsetup{ #3 }
127     }
128   }
129 }

```

(End definition for `\avmdefinecommand`. This function is documented on page 8.)

`\tl_if_eq:VnTF` A useful variant for comparing the values of token list variables with token lists.

```
130 \cs_generate_variant:Nn \tl_if_eq:nnTF {VnTF}
```

(End definition for `\tl_if_eq:VnTF`.)

`\l__avm_in_first_column` A boolean to check whether we are in the first column (value `true`) or in the second (value `false`).

```
131 \bool_new:N \l__avm_in_first_column
```

(End definition for `\l__avm_in_first_column`.)

`__avm_init_first_column:` These macros apply the settings for the columns in a (sub-)structure. They take care of font selection and report the currently active column back to the system. Knowing which column is active is important when closing the (sub-)structure. If the structure is closed without a second column present, we need to skip back 2`\tabcolsep`. (This does not apply to the case of vector structures, which are handled without this check.)

```
132 \cs_new:Nn \__avm_init_first_column:
133 {
134   \bool_set_true:N \l__avm_in_first_column
135   \normalfont\__avm_font_attribute:
136 }
137
138 \cs_new:Nn \__avm_init_second_column:
139 {
140   \bool_set_false:N \l__avm_in_first_column
141   \normalfont\__avm_font_value:
142 }
143
144 \cs_new:Nn \__avm_init_single_column:
145 {
146   \normalfont\__avm_font_attribute:
147 }
148
```

(End definition for `__avm_init_first_column:`, `__avm_init_second_column:`, and `__avm_init_single_column:`.)

`__avm_deinit_first_column:` These commands control settings that are applied after each column is exited. The single check here is whether italics is currently in use. If it is, the the italic correction is automatically applied. This replaces the user-configurable setting `apptovalues` from previous versions.

```
149
150 \tl_const:Nn \l__avm_italics_tl {it}
151
152 \cs_new:Nn \__avm_deinit_first_column:
153 {
154   \tl_if_eq:NNT \f@shape \l__avm_italics_tl {\ /}
155 }
156
157 \cs_new:Nn \__avm_deinit_second_column:
158 {
159   \tl_if_eq:NNT \f@shape \l__avm_italics_tl {\ /}
160 }
161
```

```

162 \cs_new:Nn \__avm_deinit_single_column:
163 {
164   \tl_if_eq:NNT \f@shape \l__avm_italics_tl {\}/
165 }

```

(End definition for __avm_deinit_first_column: and __avm_deinit_second_column:.)

__avm_kern_unused_columns: A helper macro to fill the horizontal space if a row is ended prematurely, i.e. if no & is present.

```

166 \cs_new:Nn \__avm_kern_unused_columns:
167 {
168   \bool_if:NTF \l__avm_in_first_column
169     { \span\hspace*{-2\tabcolsep} }
170     { }
171 }

```

(End definition for __avm_kern_unused_columns:.)

__avm_extra_skip: This function is used together with the delimiter replacements. It checks whether the delimiter is followed by a line break, in which case an extra skip is automatically inserted

```

172 \cs_new:Nn \__avm_extra_skip:
173 {
174   \peek_meaning_ignore_spaces:NTF \ \ {\vspace*{\l__avm_extra_skip_dim}} {}
175 }

```

(End definition for __avm_extra_skip:.)

__avm_module_begin: The replacement instructions for __avm_parse:n. When option $\langle align = true \rangle$ (default), the structure has two columns. Vector structures are inserted if $\langle align = false \rangle$.

__avm_module_end:

etc.

```

176 \cs_new:Nn \__avm_module_begin:
177 {
178   \bool_if:NTF \l__avm_align_bool

489 }
490 }

```

(End definition for `\tag` and others. These functions are documented on page 3.)

`__avm_parse:n` Finally, the parser. It is build on `\@@_act:NNNnn` from `l3tl` (see the sub-section *Token by token changes*). Many thanks to Phelype Oleinik for help on this, and in particular on help with expansion.

```
